GLOBAL COMPARATIVE ANALYSIS

Global Life Expectancy Paradox

AComparative Analysisof Country-LevelData: Initial Findings and Insights from the Cleaned Dataset

PURPOSE

Aim of The Analysis

This study aims to examine the differences in life expectancy across countries by analysing a range of economic, healthcare, educational, social, demographic, technological, and environmental indicators. The analysis begins with an assessment of the original dataset, followed by an investigation of the cleaned dataset to identify meaningful patterns and relationships. The primary objective is to determine the extent to which a country's economic wealth influences life expectancy and to explore the role of other factors that may contribute to differences in longevity.

Initial Review of the Original Dataset

Myinitial step involved assessingthesize, coverage,andoverall qualityofthe original dataset.The preliminarydataquality checksrevealed several inconsistencies and missing values, highlightingthe need for data cleaning before conducting reliable comparisons of life expectancy across countries.

What I checked	Finding
Rows and columns	204 rows × 38 columns
Distinct country names	192
Exact duplicate rows	12
Blank cells	305
Regions represented	22

Missing Data in the Original Dataset

The missingvaluesare unevenlydistributed across the indicators, withcertain variablescontaining more gaps thanothers.This is importantbecause indicators witha higherproportion of missingdata may have fewer countries available for comparison, potentially affecting the consistency and reliability of the analysis.

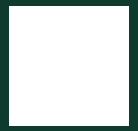

Indicator	Missing values
co2	59
Post-secondary enrollment (female)	33
Post-secondary enrollment (male)	33
Homicide rate	23
Refugees	14

HIGHEST OBSERVED GAP

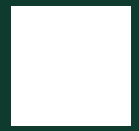

59 co2 missing values

From the Original Dataset to the Cleaned Dataset

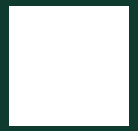

Afterremoving 12 exact duplicate rows,thedataset was reduced from 204to 192countryrecords. The cleaned dataset used in myanalysis contains20 selected variables, including male and female life expectancy. It also incorporates key indicators such as GDP per capita, infant mortality, fertility rate, internet usage, school enrollment, unemployment, urban population, forested area, and co2 emissions. This refined dataset provides a more consistent basis for comparing countries and examining factors associated with life expectancy. However, careful consideration of missing values and the accuracy of country identifiers remains essential to ensure reliable results.

204 rows × 38 columns

192 country records

20 selected variables

What Life Expectancy Looks Like

Theanalysis of thecleaned datasetindicates that female lifeexpectancyishigher than male life expectancy in terms of both the mean and median values. However,considerable variation exists across countries, highlighting the differences in life expectancy between populations and the need to examine the factors that may contribute to these disparities.

Measure	Male life expectancy	Female life expectancy
Mean	69.64 years	74.51 years
Median	70.55 years	76.55 years
Minimu	50.4 years	54.8 years
m	81.7 years	87.5 years
Maxim

The Paradox: Wealth Is Not the Whole Story

GDPper capita showsconsiderable variation across countries, with a mean of approximately US$15,500 and a median of around US$5,900. This difference suggests that a relatively small number of high-income countries raise the average, making the median a more representative measure of the typical country's economic position. Although economic resources may influence life expectancy, they do not provide a complete explanation for differences in longevity. Factors such as healthcare conditions, infant mortality, education, fertility, technological access, and overall living standards must also be considered. Therefore, my analysis examines these indicators collectively to develop a broader understanding of the global life expectancy paradox, rather than attributing differences in life expectancy to economic wealth alone.

US$15,500

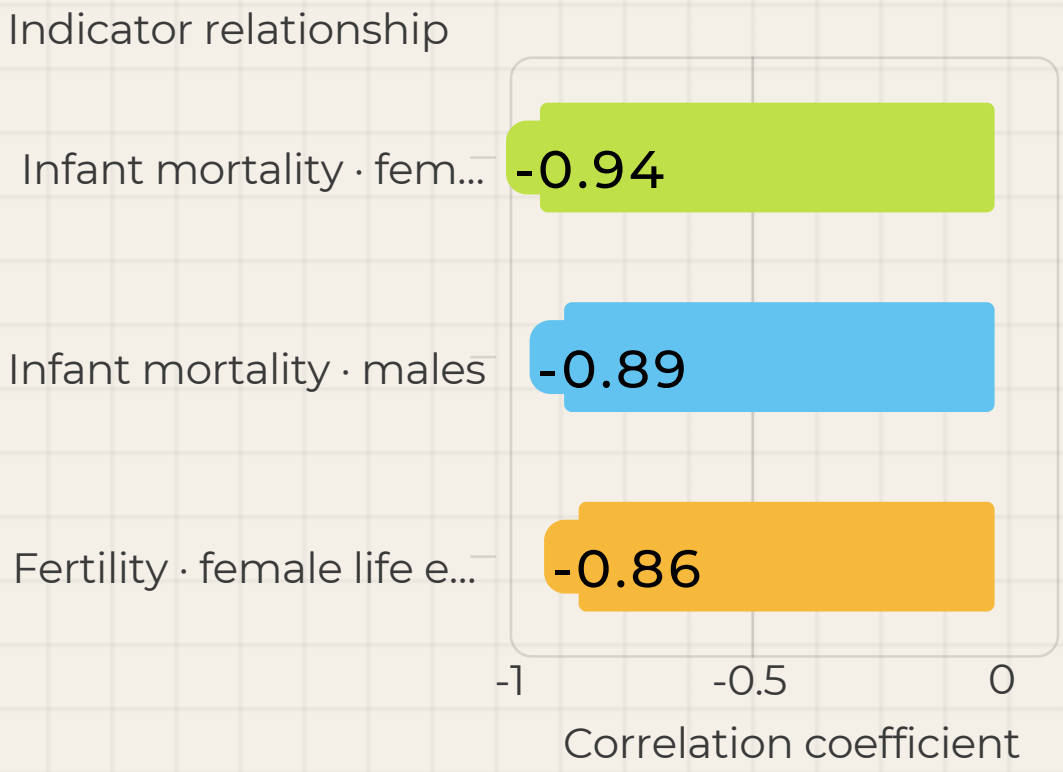

mean

US$5,900

median

Health and Social Indicators Show Strong Links

Thecorrelationanalysisrevealsastrong negative relationship between infant mortalityand life expectancy, with correlation coefficients of −0.94 for females and −0.89 for males. Female life expectancy also exhibits a strong negative correlation with fertility, with a coefficient of −0.86. These findings indicate that countries with higher infant mortality and fertility rates tend to have lower life expectancy. The observed relationships highlight the importance of considering broader health and demographic indicators when investigating differences in life expectancy across countries. However, these correlations indicate associations rather than direct causal relationships.

Technology, Education and Living Conditions

Internet usage andschoolenrollmentoffer additional perspectives for examining differences in development acrosscountries.The correlation analysisshows astrong positive relationship between male and female school enrollment (0.97), as well as between male and female life expectancy (0.96). These strong associations suggest that related indicators may reflect overlapping underlying patterns rather than entirely independent influences. Therefore, my analysis considers these variables alongside healthcare indicators and GDP per capita to gain a more comprehensive understanding of differences in life expectancy across countries.

Next steps

1. My next stepis toexamine the relationship between life expectancy and key indicators, including GDP per capita, infant mortality, fertility, internet usage, and school enrollment.

2. I will investigate whether countries with comparable GDP per capita levels exhibit substantial differences in life expectancy, while also examining regional patterns and the number of countries represented in each region.

3. Where possible, I will repeat the key comparisons using both imputed and non-imputed values to assess the impact of missing-data treatment on the findings.

4. Throughout the analysis, I will acknowledge limitations related to data availability, regional representation, and the interpretation of correlations, ensuring that the conclusions remain balanced and evidence-based.
